## HEATING HELPERS

Be certain that windows are shut tightly.  
If your windows won't shut properly call  
**Facilities Management at x2012** to report  
the problem. We will fix it.

Drawing the window blind will help to  
slow heat losses during the OFF cycles of  
the heating operation.

If your room has a temperature sensor in  
it TRY NOT to locate heat producing de-  
vices like a lamp near it. This can se-  
verely limit the heat to the building.

Call the Central Heating Plant  
@ x2016

Mount Holyoke consumes in ½  
hour more electricity than a  
typical 5 room house does in  
an entire month.

**This is about 750 kilo-  
watt-hours.**

Mount Holyoke consumes  
more than 38,000 kilowatt-  
hours of electricity per day.

**This is enough electric-  
ity to supply a 5 room house  
for 4.2 years, or maintain 50  
of these houses for a month.**

Mount Holyoke burned  
940,000 thousand gallons of  
Oil last year, for heat and hot  
water.

**This would heat more  
than 1500 homes for a year. Or,  
a single home for more than  
1,500 years.**

## WHERE'S THE HEAT COME FROM?

The entire campus is heated with steam that is produced in the Central Heating Plant and then distributed to every building via underground pipes.

At the peak of the season approximately 6,500 gallons of #6 Fuel Oil is burned every day to make the steam required to heat our buildings. This steam is maintained at very high pressures and is used first to generate electricity before being utilized by the campus for heating purposes. This generated electricity is applied against the consumption of Utility (purchased) power.

Underground distribution piping brings the steam to each building where it's pressure is reduced and made useable for the various heating systems.

Once the steam has released it's energy it returns to the CHP as condensate, to be re-heated for another cycle. About 90% of the steam returns as water for re-use.

**The Energy Management Computer watches for heat and cold around the clock**

## IT'S A CIRCULATED HOT WATER HEATING SYSTEM

Ham Hall is heated with circulated hot water and Fin Tube Radiation. Steam from the Central heating Plant is piped into the building where it is used to heat the circulated water. The water is then pumped around the building to heat the spaces.

Sensors located throughout the building monitor the room temperatures and report that information to an Energy Management Computer System also located in the basement. This information is transmitted to a Master Computer System in the Central Heating Plant where it is checked against a heating program dedicated to the Ham environment. The automatic valves respond to this program to maintain the spaces at Setpoint ( the equivalent of a Thermostat setting).

The Engineer operating the Heating Plant when necessary can override this program.

Along the outside wall of each room is a section of Fin-Tube Radiation. The radiation is behind a face board with an opening at the top and at the bottom that allows air to flow over the hot pipes. This design depends upon a clear path for the air to naturally enter and exit the radiation area in order to heat the room. Cool air from the floor area enters the bottom of the heater where it is heated as it passes by the fin-tube piping. The warm air then rises out of the heater and into the room, displacing any cooler air so that the cycle can repeat itself. This type of heating is called *CONVECTION*.

There is no individual control for a system like this. Any change to the flow of hot water through a single piece of radiation would have a significant effect on all the radiation on the same piping loop. This system is balanced when first installed and remains so unless changes are made to the piping system.

This system provides for generally even space temperatures and compensates for changes in outside conditions.
